4
5
6 22 Nonverbal synchrony of facial movements and expressions predict therapeutic alliance
7
8
9 23 during a structured psychotherapeutic interview

10
11 24 **Introduction**

12
13
14 25 Humans synchronize nonverbally with others during interactions (Repp & Su, 2013) in
15
16
17 26 terms of posture, facial movements (Semin & Cacioppo, 2008), and even breathing
18
19
20 27 patterns (McFarland, 2001). This is referred to as nonverbal synchrony (NVS; Condon
21
22
23 28 & Ogston, 1966). Many studies have found that NVS can strengthen collaborative
24
25
26 29 relationships between two adults (Chartrand & Lakin, 2013). Recent studies have
27
28
29 30 measured NVS precisely within a short time without a human rater's bias (Bernieri,
30
31
32 31 Davis, Rosenthal, & Knee, 1994) through video imaging techniques (Ramseyer &
33
34
35 32 Tschacher, 2011; Schmidt, Morr, Fitzpatrick, & Richardson, 2012) and have enabled
36
37
38 33 clarification of the link between NVS of body/head parts and collaborative relationships
39
40
41 34 (Won, Bailenson, Stathatos, & Dai, 2014). However, such studies have primarily
42
43
44 35 focused on body/head parts; the link between NVS of face parts and collaborative
45
46
47 36 relationships remains unclear, even though an electromyography study established the
48
49
50 37 link between NVS of face parts and willingness for future interaction (Riehle & Lincoln,
51
52
53 38 2018). Clarification of this link through a video image method is important to fully
54
55
56 39 understand NVS and contribute to the understanding of nonverbal behavior in dyadic
57
58
59 40 relationships (Riehle, Kempkensteffen, & Lincoln, 2017; Schmidt et al., 2012; Won et

60
61
62
63
64
65

1
2
3 41 al., 2014). Accordingly, our study clarified the link between NVS of face parts and
4
5
6 42 collaborative relationship during structured psychotherapeutic interviews.
7

8 9 43 **Nonverbal Synchrony and Collaborative Relationship**

10
11 44 On the basis of social cognition theory (Semin & Cacioppo, 2008), our rationale
12
13
14 45 was that one's NVS with the other encourages perceived social unity and a collaborative
15
16
17 46 relationship with the other. Indeed, a study found that people who watched and
18
19
20 47 experienced a stranger's nonverbal behavior synchronously reported social unity with
21
22
23 48 the stranger and perceived physical and personal resemblance to the stranger more
24
25
26 49 strongly than those who experienced asynchronous nonverbal behavior (Paladino,
27
28
29 50 Mazzurega, Pavani, & Schubert, 2010). An empirical review indicated that NVS
30
31
32 51 between two persons is linked with liking, empathy, and a feeling of closeness
33
34
35 52 (Chartrand & Lakin, 2013). Meta-analysis of NVS also supported the link between NVS
36
37
38 53 and collaborative relationships (Vicaria & Dickens, 2016).
39

40
41 54 The link between NVS and collaborative relationships was confirmed in
42
43
44 55 community settings (Chartrand & Bargh, 1999). NVS is positively linked with social
45
46
47 56 unity (Miles, Lumsden, Richardson, & Neil Macrae, 2011), self-disclosure
48
49
50 57 (Vacharkulksemsuk & Fredrickson, 2012), and collaborative intentions, regardless of
51
52
53 58 whether the intentions are conscious (Shockley, Santana, & Fowler, 2003) or
54
55
56 59 unconscious (Lakin & Chartrand, 2003). High school teachers who perceive a
57
58
59 60 collaborative relationship with their students show more NVS than those without such a
60
61
62
63
64
65

1
2
3 61 relationship (Bernieri, 1988). Adults who feel positive affect during a conversation with
4
5
6 62 a stranger also show NVS with the stranger more frequently than those who do not feel
7
8
9 63 positive affect (Tschacher, Rees, & Ramseyer, 2014). These findings validate the link
10
11
12 64 between NVS and collaborative relationships in a community setting.

13
14 65 The link between NVS and collaborative relationships was also found in clinical
16
17 66 settings (Riehle & Lincoln, 2018), although the collaborative relationship in clinical
18
19
20 67 settings was referred to as therapeutic alliance (Martin, Garske, & Katherine, 2000).
21
22
23 68 One study analyzed 70 outpatients who took part in approximately 40 psychotherapy
24
25
26 69 sessions per patient and found that NVS between the patients and their therapists during
27
28
29 70 the sessions was positively linked with their therapeutic alliance (Ramseyer &
30
31
32 71 Tschacher, 2011). Outpatients whose conditions improved during psychotherapy
33
34
35 72 sessions also showed higher NVS with their therapists than those who dropped out
36
37
38 73 during the sessions (Paulick et al., 2017). A review of NVS in clinical fields suggested
39
40
41 74 NVS between therapist and client as a marker of therapeutic alliance (Tschacher &
42
43
44 75 Pfammatter, 2016), with several exceptions (Kupper, Ramseyer, Hoffmann, &
45
46
47 76 Tschacher, 2015; Lavelle, Healey, & McCabe, 2013; Paulick et al., 2018).

48
49 77 The link between NVS and therapeutic alliance has been corroborated (Paulick et
50
51
52 78 al., 2017; Ramseyer & Tschacher, 2011; Tschacher & Pfammatter, 2016); however, a
53
54
55 79 previous NVS study that used a video imaging technique mainly focused on body parts,
56
57
58 80 movement perspective, and total volume of synchrony (absolute value of synchrony). In
59
60
61
62
63
64
65

1
2
3 81 other words, the NVS studies that use video imaging techniques rarely report face parts,
4
5
6 82 expression perspective, and direction of synchrony (positive or negative value of
7
8
9 83 synchrony), even though many studies indicated the importance of these parts,
10
11
12 84 perspective, and direction (Ekman, 2003; Riehle et al., 2017; Riehle & Lincoln, 2018).
13
14
15 85 Hence, the current study formulated research questions and hypotheses with this regard.
16
17
18 86 Exploration of these research questions contributed to the body of knowledge by
19
20
21 87 extending NVS location (face), meaning (emotional expression), and index
22
23
24 88 (symmetrical or complementary) (Kupper et al., 2015; Paulick et al., 2018; Ramseyer &
25
26
27 89 Tschacher, 2011, 2014; Tschacher et al., 2014).

90 **Nonverbal Synchrony of Facial Movements and Therapeutic Alliance**

91 Previous NVS studies through video imaging techniques (Ramseyer & Tschacher, 2011)
92 primarily focused on the body/head area (Kupper et al., 2015; Paulick et al., 2017;
93 Tschacher et al., 2014); as such, it is unclear whether NVS of face parts is linked with
94 therapeutic alliance. Our study defined facial movements as physical movements of face
95 parts (e.g., eye movements) without any emotional message conveyed by the
96 movements (Ekman & Friesen, 1976). Hence, NVS of facial movements indicates
97 synchrony of the physical movements between two persons. NVS of facial movements
98 was a hot topic in an NVS study (Riehle et al., 2017; Riehle & Lincoln, 2018). Hence,
99 our first research question is, “Is NVS of facial movements linked with therapeutic
100 alliance?”(RQ1) One study using a video imaging technique found that synchrony of

1
2
3 101 head movements was positively correlated with therapeutic alliance, although the
4
5
6 102 correlation did not reach a significant level (Ramseyer & Tschacher, 2014). Facial
7
8
9 103 movements are key components of nonverbal behavior (Ekman, 2003). Hence, it is
10
11
12 104 possible that NVS of facial movements could show correlations similar to the NVS of
13
14
15 105 other areas, such as head and body movements. Hence, we hypothesized that NVS of
16
17
18 106 facial movements would be positively correlated with therapeutic alliance (Hypothesis
19
20
21 107 1).

22 23 108 **Facial Movements and Facial Expressions**

24
25
26 109 The previous NVS studies that used video imaging techniques encoded movements only
27
28
29 110 (Kupper et al., 2015; Paulick et al., 2018), with one exception (Lozza et al., 2018), so
30
31
32 111 that emotional messages conveyed through the movements were still unclear. We
33
34
35 112 defined facial expressions as emotional messages conveyed through facial movements,
36
37
38 113 such as a happy message through one's smile (Ekman, 1993). Hence, NVS of facial
39
40
41 114 expressions indicates synchrony of emotional messages between two persons. A
42
43
44 115 previous study suggested that a specific emotional message can be interpretable from
45
46
47 116 specific muscle movements (Riehle et al., 2017). Actually, occurrences of specific facial
48
49
50 117 movements indicate the occurrence of a specific emotional message (Ekman, 2003).
51
52
53 118 Still, the occurrences of facial movements and emotional messages were measured
54
55
56 119 through a discrete variable (e.g., 0 or 1) but not a continuous variable (e.g., 0 to 1). Our
57
58
59 120 second research question is, "Are continuous movements of face parts linked with
60
61
62
63
64
65

1
2
3 121 continuous emotional messages of the face?” Eye movements have previously been
4
5
6 122 linked to negative emotional expressions (Baron-Cohen, Wheelwright, Hill, Raste, &
7
8
9 123 Plumb, 2001); for instance, widened and narrowed eyes are considered to represent fear
10
11
12 124 and disgust, respectively (Lee, Mirza, Flanagan, & Anderson, 2014). Another study also
13
14
15 125 shows the link between eye movements and negative emotions, such as confusion and
16
17
18 126 frustration (D’Mello, Picard, & Graesser, 2007). Hence, we hypothesized that eye
19
20
21 127 movements could be correlated with negative emotional expression (Hypothesis 2).

22 23 128 **Complementary and Symmetrical Synchrony**

24
25
26 129 Previous NVS studies focused on absolute values of synchrony (Kupper et al., 2015;
27
28
29 130 Paulick et al., 2017; Ramseyer & Tschacher, 2011; Tschacher et al., 2014), whereas they
30
31
32 131 did not differentiate the direction (positive and negative values) of synchrony. A positive
33
34
35 132 value of synchrony consists of a symmetrical synchrony (Watzlawick, Bavelas, &
36
37
38 133 Jackson, 2011), in which one sends a message and the recipient returns the same
39
40
41 134 message. In case of facial movement, when one’s amplitude of facial movement reaches
42
43
44 135 a crescendo, the other’s amplitude of facial movement also reaches a crescendo. In case
45
46
47 136 of a facial expression, when one smiles strongly, the other also smiles strongly. Contrary
48
49
50 137 to symmetrical synchrony, a negative value of synchrony consists of a complementary
51
52
53 138 synchrony, in which one sends a message and the recipient returns another message
54
55
56 139 (Watzlawick et al., 2011). In case of facial movements, when one’s amplitude of facial
57
58
59 140 movement reaches a crescendo, the other’s amplitude of facial movement falls to a
60
61
62
63
64
65

1
2
3 141 minimum. In case of facial expressions, when one smiles strongly, the other displays
4
5
6 142 anger strongly.
7

8
9 143 Many studies have evaluated these directions of synchrony and reported their
10
11 144 different functions in the psychotherapeutic field (Erchul et al., 1999; Fraser, Vachon,
12
13
14 145 Hassan, & Parent, 2016; Rogers & Farace, 1975) but not yet in the NVS field. Hence,
15
16
17 146 our third research question is, “Are complementary and symmetrical synchrony of the
18
19
20 147 face linked differently with therapeutic alliance?” A previous study found positive
21
22
23 148 effects of complementary synchrony on collaborative relationships and negative effects
24
25
26 149 of symmetrical synchrony (Rogers & Farace, 1975). For example, a complementary
27
28
29 150 synchrony of leadership, where one takes leadership and the other takes followership, is
30
31
32 151 linked with a collaborative relationship (Erchul et al., 1999). In contrast, a symmetrical
33
34
35 152 synchrony of leadership, where both people take leadership, is linked with a conflict
36
37
38 153 relationship. These findings were also corroborated in couple relationships (Escudero,
39
40
41 154 Rogers, & Gutierrez, 1997) and therapeutic relationships (Heatherington & Friedlander,
42
43
44 155 1990). Complementary and symmetrical synchronies are observable in any
45
46
47 156 communication (Watzlawick et al., 2011); consequently, we hypothesized that the
48
49
50 157 symmetrical synchrony of facial movements would be negatively correlated with
51
52
53 158 therapeutic alliance, whereas complementary synchrony of facial movements would be
54
55
56 159 positively correlated with therapeutic alliance (Hypothesis 3A). Similarly, we
57
58
59 160 hypothesized that the symmetrical synchrony of facial expressions would be negatively
60
61
62
63
64
65

1
2
3 161 correlated with therapeutic alliance, whereas complementary synchrony of facial
4
5
6 162 expression would be positively correlated with therapeutic alliance (Hypothesis 3B).
7
8

9 **163 Prediction of Therapeutic Alliance through Nonverbal Synchrony of Facial**
10
11 **164 Movements and Facial Expressions**
12

13
14 165 Most NVS analyses of movements (Kupper et al., 2015; Paulick et al., 2017; Ramseyer
15
16
17 166 & Tschacher, 2011; Tschacher et al., 2014) and expressions (Riehle et al., 2017; Riehle
18
19
20 167 & Lincoln, 2018) were carried out separately; almost none were performed together.
21
22
23 168 Hence, the effects of facial movements and expressions on therapeutic alliance were
24
25
26 169 unclear. The fourth research question is, “Do NVS of facial movements and expressions
27
28
29 170 predict therapeutic alliance?” To avoid multicollinearity (Graham, 2003), we selected
30
31
32 171 eye movements from facial movements because eye movements were the representative
33
34
35 172 of facial movements (Baron-Cohen et al., 2001; Lee et al., 2014). Similarly, we selected
36
37
38 173 happy and scared expressions from facial expressions because the happy and scared
39
40
41 174 expressions were also the representatives of facial expressions (Ekman, 2003; Riehle &
42
43
44 175 Lincoln, 2018). Further, participants’ age, sex, the volume of facial expressions, and the
45
46
47 176 volume of facial movements were controlled because they might affect therapeutic
48
49
50 177 alliance (Elvins & Green, 2008; Martin et al., 2000). We hypothesized that NVS of
51
52
53 178 facial movements and expressions would predict therapeutic alliance even after
54
55
56 179 participants’ age, sex, the volume of facial expressions, and the volume of facial
57
58
59 180 movements were controlled (Hypothesis 4).
60
61
62
63
64
65

1
2
3 **181 Aims**
4
5

6 182 Before testing these hypotheses, we inspected whether genuine synchrony [synchrony
7
8
9 183 between real pairs] of facial movements and expressions is different from pseudo
10
11
12 184 synchrony [synchrony between random pairs] of facial movements and expressions
13
14
15 185 (Gatewood & Rosenwein, 1981). Similar to a previous study (Ramseyer & Tschacher,
16
17
18 186 2014; Riehle et al., 2017), we hypothesized that synchrony of facial movements and
19
20
21 187 expressions for the genuine pair would be different from the synchrony of the pseudo
22
23
24 188 pair (Hypothesis 0). The current study aims to test these hypotheses.

25
26 189 To evaluate participants' facial movements, we used dlib (King, 2009) and
27
28
29 190 OpenCV (Bradski & Kaehler, 2000) as the program packages because they have been
30
31
32 191 used in clinical settings and are well validated (Yokotani, Takagi, & Wakashima, 2018).
33
34
35 192 To evaluate participants' facial expressions, we utilized a convolutional neural network
36
37
38 193 model for an emotion recognition task (Arriaga, Valdenegro-Toro, & Plöger, 2017). The
39
40
41 194 convolutional neural network model was common for detection tasks of the human face
42
43
44 195 and human emotion (Levi & Hassner, 2015; Matsugu, Mori, Mitari, & Kaneda, 2003).
45

46
47 **Methods**
48

49 **197 Participants**
50
51

52 198 The present participants were the same as those in a previously published study
53
54
55 199 (Yokotani et al., 2018); however, the sampling of video images and analysis methods
56
57
58 200 were different. The 57 Japanese university students were recruited by asking a
59
60
61
62
63
64
65

1
2
3 201 university professor to make an announcement during a psychology class, and through
4
5
6 202 snowball sampling that involved identifying students' friends through referrals. Of the
7
8
9 203 57 students, two were excluded because one refused to participate and the other did not
10
11
12 204 work at our laboratory; consequently, our final sample comprised 55 students. All of the
13
14
15 205 participants provided written informed consent and received a gift card (1,500 Japanese
16
17
18 206 yen, around 12 Euro) in return for their participation. They received no prior
19
20
21 207 information regarding our research questions.
22

23 208 Of the 55 students, 30 were female and 25 were male, and their average age
24
25
26 209 was 22.92 years (*S.D.* 2.82). All participants were native Japanese speakers and were
27
28
29 210 not regular patients at mental hospitals or counseling centers. A male Japanese clinical
30
31
32 211 psychologist with a doctorate degree in philosophy conducted the Structured Clinical
33
34
35 212 Interview for Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition,
36
37
38 213 Text Revision Axis I disorders, Non-patient Edition (First, Spitzer, Gibbon, & Williams,
39
40
41 214 1997), using the Japanese version (First et al., 2010). The psychologist had over 10
42
43
44 215 years' experience in the mental health field and had conducted psychological treatment
45
46
47 216 sessions for the inmates of a Japanese prison, as well as mental evaluations for the
48
49
50 217 accused in a Japanese court (Yokotani & Tamura, 2015, 2016). The participants' mean
51
52
53 218 score for global assessment of functioning was 70.25 (*S.D.* 7.98); hence, the majority of
54
55
56 219 participants belonged to a non-clinical sample (Aas, 2011).

57
58 220 **Questionnaires**
59
60
61
62
63
64
65

1
2
3 221 A previous study recommended assessment of therapeutic alliance using participants'
4
5
6 222 responses on a self-report questionnaire (Elvins & Green, 2008). As such, we used a
7
8
9 223 self-report questionnaire to assess therapeutic alliance (Kakii, 1997). The questionnaire
10
11
12 224 consisted of two items (1. I felt that the counselor created a warm atmosphere; 2. I felt
13
14
15 225 familiarity with the counselor) that were rated using a five-point scale (1 to 5).
16
17
18 226 Participants were asked to respond to this questionnaire, after they had completed the
19
20
21 227 interviews. The average score of the two items was 4.44 (S.D. 0.63). To validate the
22
23
24 228 questionnaire, participants also answered an additional four-item questionnaire using the
25
26
27 229 five-point scale. The first two questions pertained to transmission of information (e.g.,
28
29
30 230 item 1: I felt that what I wanted to say was transmitted to the counselor) and the last two
31
32
33 231 questions pertained to transmission of emotion (e.g., item 4: I felt that the counselor
34
35
36 232 understood my feelings). The therapeutic alliance scores were positively correlated with
37
38
39 233 transmission of information ($r = .444, p < .001$) and transmission of emotion ($r = .502,$
40
41
42 234 $p < .001$), respectively.

235 **Sampling of video images for facial movements**

236 Participants were interviewed by the clinical psychologist in an experimental room (Fig.
237 1A). During the interview, both the participants' and the therapist's facial movements
238 were video recorded. All videos recorded during the conversation (1280×720 pixels,
239 29.9 frames per second) were converted into a series of pictures that represented one
240 image for every 100 milliseconds of video (Fig. 1B-1: therapist's face). Participants' and

1
2
3 241 therapist's head movements change the face coordinates, regardless of actual facial
4
5
6 242 movements (Fig.2). To minimize the effects of their head movements on their facial
7
8
9 243 movements, we used an affine formula (Fig.2). All faces were transformed to one
10
11
12 244 averaged female face image (530×530 pixels) (Langlois & Roggman, 1990) (Fig.1B-2,
13
14
15 245 B-3). To determine facial landmarks of the transformed faces, we used OpenCV and
16
17
18 246 dlib (King, 2009), which identified 68 landmarks for each picture (Fig.1B-4). Fig. 3
19
20
21 247 indicates actual ranges of numbers that cover specific facial parts. The number of
22
23
24 248 participants' pictures was 1,258,716. For some pictures (5.99 %), we were unable to
25
26
27 249 detect their facial landmarks perfectly because the landmarks were sometimes covered
28
29
30 250 during conversation. The missing facial landmarks in these pictures were estimated
31
32
33 251 using a multiple imputation method (Sterne et al., 2009). The therapist's missing facial
34
35
36 252 landmarks were estimated in the same manner.

37
38 253 A previous NVS study regarding body movements utilized the first 900
39
40
41 254 seconds of interviews (Paulick et al., 2017; Ramseyer & Tschacher, 2011; Tschacher et
42
43
44 255 al., 2014). To be similar to these studies, we used the first 910 seconds of interviews.
45
46
47 256 Further, a previous NVS study regarding facial expressions recommended a 7-second
48
49
50 257 frame as a time window size (Riehle et al., 2017). Hence, we divided the interview into
51
52
53 258 7-second portions; a portion involves 70 faces. The final dataset consisted of
54
55
56 259 participants' 7150 seven-second portions involving their 500,500 face images and their
57
58
59 260 therapist's 7150 seven-second portions involving his 500,500 face images.
60
61
62
63
64
65

1
2
3 **261 Quantification of facial movements**
4
5

6 262 We calculated absolute differences in facial landmarks between each picture and a
7
8
9 263 previous picture (i.e., the picture that was taken 100 milliseconds prior to the current
10
11
12 264 one). When the landmarks between the two pictures differed along the X axis, we
13
14
15 265 scored the difference as horizontal movement. $X_{k,n}$ is the x coordinate at time n at
16
17
18 266 position k ; K indicates all positions in specific areas. For the right eyebrow, K contains
19
20
21 267 positions from 18 to 22 (Fig.3). Similarly, when the landmarks differed along the Y axis,
22
23
24 268 we scored the difference as vertical movement. The average of horizontal and vertical
25
26
27 269 movements was regarded as the movement of a specific area. High movement scores
28
29
30 270 indicated a high frequency and wide variety of movements.

31
32
33 271
$$m[n] = \frac{1}{2|K|} \left(\sum_{k \in K} |X_{k,n+1} - X_{k,n}| + |Y_{k,n+1} - Y_{k,n}| \right)$$

34
35
36
37

38 272 The averages of these movements during the first 910 seconds of interviews were also
39
40
41 273 used as an average facial movement score during a session.

42
43
44 274
$$\bar{m} = \frac{1}{2|K|} \cdot \frac{1}{N-1} \left(\sum_{n \in N-1} \sum_{k \in K} |X_{k,n+1} - X_{k,n}| + |Y_{k,n+1} - Y_{k,n}| \right)$$

45
46
47
48

49 275 N indicates the total number of pictures in a session (9,100). Hence, the average facial
50
51
52 276 movement scores were constant during the session. Fig. 1C shows pairs of one
53
54
55 277 participant's facial movements and the therapist's facial movements for 200 frames (20
56
57
58 278 seconds). Fig. 1D compares a participant's ($m_{par}[n]$) and the therapist's ($m_{th}[n]$) left
59
60
61
62
63
64
65

1
2
3 279 eye movements for the same 200 frames.
4
5

6 280 **Quantification of Complementary, Symmetrical, and Absolute synchrony for**
7
8
9 281 **Facial Movements**

10
11 282 Cross-correlation coefficients between the participants' and therapist's facial
12
13
14
15 283 movements were computed using the following formula:

16
17 284
$$\varphi_{par,th}[j] = \{m_{par}[n - \min(j, 0)] - \overline{m_{par}}\} \{m_{th}[n + \max(j, 0)] - \overline{m_{th}}\}$$

18
19
20 285 $m_{par}[n]$ and $m_{th}[n]$ represent the participant's and therapist's facial movements at
21
22
23 286 time n . $\overline{m_{par}}$ and $\overline{m_{th}}$ are the averages of the facial movements. j represents time lags
24
25
26 287 between the participant and therapist, which ranged from -20 to +20 frames (one frame
27
28
29 288 is 100 milliseconds) as recommended by previous studies (Riehle et al., 2017; Riehle &
30
31
32 289 Lincoln, 2018). Negative j values indicate that the participant's facial movements
33
34
35 290 occurred after j frames of the therapist's facial movements. Positive j values indicate
36
37
38 291 that the therapist's facial movements occurred after j frames of the participant's facial
39
40
41 292 movements. In short, negative and positive j values indicate a delayed response by the
42
43
44 293 participant and therapist, respectively.

45
46
47 294 To distill symmetrical, complementary, and absolute synchrony, we utilized the
48
49 295 following formula:

50
51
52
53 296
$$\text{sym}[j] = \sum_{n=1}^{M-1-|j|} \max(0, \varphi_{par,th}[j])$$

$$297 \quad \text{comp}[j] = - \sum_{n=1}^{M-1-|j|} \min(0, \varphi_{par,th}[j])$$

$$298 \quad \text{abs}[j] = \sum_{n=1}^{M-1-|j|} |\varphi_{par,th}[j]|$$

$$299 \quad \text{self}_{par}[j] = \sum_{n=1}^{M-1-|j|} \{m_{par}[n - \min(j, 0)] - \overline{m_{par}}\}^2$$

$$300 \quad \text{self}_{th}[j] = \sum_{n=1}^{M-1-|j|} \{m_{th}[n + \max(t, 0)] - \overline{m_{th}}\}^2$$

301 M is the total number of pictures within a seven-second interval (70). $\text{Sym}[j]$ includes
 302 only positive values of $\varphi_{par,th}[j]$, whereas $\text{comp}[j]$ includes only negative values of
 303 $\varphi_{par,th}[j]$. $\text{Abs}[j]$ include all $\varphi_{par,th}[j]$ as absolute values (Ramseyer & Tschacher,
 304 2011). $\text{self}_{par}[j]$ and $\text{self}_{th}[j]$ were variances of the participants' and therapist's
 305 movements at t time lag, respectively.

306 The cross-correlation coefficients were also normalized (Yoo & Han, 2009) and
 307 these values were referred to as SYM, COMP, and ABS synchrony, respectively. The
 308 formula used is more accurate than a previously reported one (Boker, Xu, Rotondo, &
 309 King, 2002) because the denominator is adjusted by the time lag.¹

$$310 \quad \text{SYM}_{par,th}[j] = \frac{\text{sym}[j]}{\sqrt{\text{self}_{th}[j]} \sqrt{\text{self}_{par}[j]}}$$

¹Previous formula in SYM is $\text{SYM}_{par,th}[j] = \frac{\text{sym}[j]}{\sqrt{\text{self}_{th}[0]} \sqrt{\text{self}_{par}[0]}}$

$$311 \quad \text{COMP}_{par,th}[j] = \frac{comp[j]}{\sqrt{self_{th}[j]}\sqrt{self_{par}[j]}}$$

$$312 \quad \text{ABS}_{par,th}[j] = \frac{abs[j]}{\sqrt{self_{th}[j]}\sqrt{self_{par}[j]}}$$

313 Fig. 4A shows SYM[j] of left eye movements between a participant and the therapist
 314 during a session. Fig. 4B shows COMP_{par,th}[j] of left eye movements between a
 315 participant and the therapist during a session. The vertical line indicates the duration of
 316 the session (one unit is 7 seconds). The horizontal line indicates time lags [j]. Negative j
 317 indicates that the participant synchronized after j frames of the therapist's facial
 318 movements. Similarly, positive j indicates that the therapist synchronized after j frames
 319 of the participant's facial movements. Their average was regarded as an indicator of
 320 genuine synchrony during the session (Fig. 4A, 4B, bold scores). Unlike a prior study,
 321 we did not use Fisher's Z-transformation (Ramseyer & Tschacher, 2011) because the
 322 synchrony values might exhibit a multimodal distribution².

323 **Sampling of video images for facial expressions**

324 The number of pictures for participants' facial expression was the same as the number
 325 of pictures for facial movements (N = 1,258,716). Still, in some participants' pictures
 326 (6.49%), we were unable to identify their facial expressions. These pictures were
 327 discarded. The missing facial expressions in these pictures were estimated using a

59 ² Fisher's Z-transformation assumes a unimodal distribution

1
2
3 328 multiple imputation method (Sterne et al., 2009). The therapist's missing facial
4
5
6 329 expressions were estimated in the same manner.

9 330 **Quantification of facial expressions**

10
11 331 To quantify facial expressions, we utilized an emotion recognition model (Arriaga et al.,
12
13 332 2017). The model consists of a fully-convolutional neural network and involves around
14
15 333 60, 000 parameters. The model learned the parameters through 28,709 gray faces with 7
16
17 334 emotion categories (Happy, Scared, Angry, Disgust, Sad, Surprised, and Neutral)
18
19 335 (Carrier, Courville, Goodfellow, Mirza, & Bengio, 2013). After 102 epochs training
20
21 336 (one epoch involves 28,709 faces), the model predicted 7 emotions of a new data set
22
23 337 (3,589 faces) at 66 percent accuracy. Fig. 5 shows examples of three faces and estimated
24
25 338 probabilities of emotional expressions on these faces (A-1, A-2, A-3, B). A high
26
27 339 probability of a specific emotional expression indicates that the face expresses emotions
28
29 340 strongly: for instance, a baby's smiling face (Fig.5 A-1) indicates 97.034 % of happiness
30
31 341 (Fig.5 B) meaning the baby strongly expressed happy emotions at the moment the
32
33 342 picture was taken.

34
35
36
37
38 343 We applied this emotional recognition machine on the therapist's and
39
40 344 participant's faces to quantify their facial expressions at the moment a picture was
41
42 345 captured. Further, application of this machine on time-varying faces (their faces during
43
44 346 interviews) also quantifies the dynamics of their facial expressions during interviews.
45
46
47 347 Fig. 5 C shows examples of therapist's faces in 20 seconds (200 frames). The model
48
49
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3 348 estimated the probability of happy and scared expressions during the 200 frames (every
4
5
6 349 frame involves one face). Fig. 5 D-1 and D-2 shows the therapist's probability of happy
7
8
9 350 and scared expressions during the 200 frames, respectively. In the same way,
10
11
12 351 participants' facial expressions were estimated: Fig.5 D-1 and D-2 shows a participant's
13
14
15 352 probability of happy and scared expressions, respectively. The therapist's and the
16
17
18 353 participant's quantified facial expressions were used to estimate the synchrony of facial
19
20
21 354 expressions. Before we estimated synchrony, we calculated the average of the facial
22
23
24 355 expressions during the interview.

25
26
27
28 356
$$\bar{e} = \frac{1}{N} \sum_{n \in N} e[n]$$

29
30
31
32 357 N is the total number of pictures during a session (9100). $e[n]$ indicates the probability
33
34
35 358 of a specific facial expression (such as a happy expression) at time n.

36
37
38 359 **Quantification of complementary, symmetrical, and absolute synchrony for facial**
39
40
41 360 **expressions**

42
43
44 361 Formulas of cross-correlation coefficients for facial expressions were mainly the same
45
46
47 362 as formulas for facial movements, although the formulas for facial expressions changed
48
49
50 363 from $m_{par}[n]$, $m_{th}[n]$, $\overline{m_{par}}$, and $\overline{m_{th}}$ to $e_{par}[n]$, $e_{th}[n]$, $\overline{e_{par}}$, and $\overline{e_{th}}$, respectively.

51
52 364
$$\varphi_{par,th}[j] = \{e_{par}[n - \min(j, 0)] - \overline{e_{par}}\} \{e_{th}[n + \max(j, 0)] - \overline{e_{th}}\}$$

53
54
55
56 365
$$self_{par}[j] = \sum_{n=1}^{M-|j|} \{e_{par}[n - \min(j, 0)] - \overline{e_{par}}\}^2$$

57
58
59
60
61
62
63
64
65

$$self_{th}[j] = \sum_{n=1}^{M-|j|} \{e_{th}[n + \max(j, 0)] - \overline{e_{th}}\}^2$$

$e_{par}[n]$ and $e_{th}[n]$ represent the participant's and therapist's facial movement at time n .

$\overline{e_{par}}$ and $\overline{e_{th}}$ are the averages of the facial movements.

Quantification of pseudo synchrony for both facial movements and expressions

The 7150 seven-second portions (70 faces in each portion) of participants' faces were randomly paired with the 7150 seven-second portions of the therapist's faces. Among them, 125 pairs were in the same session; these pairs were excluded. The other 7025 pairs never occurred in an actual interview; they were regarded as pseudo pairs. We calculated the synchrony of pseudo pairs as pseudo synchrony of facial movements. The pseudo pairs were also used to calculate pseudo synchrony of facial expressions.

Analysis

To test hypothesis 0, we used t-test and Cohen's d. Pearson's correlation was also used to test hypothesis 1, 2, 3A, and 3B. Hierarchical regression analysis was also used to test hypothesis 4. For the purpose of exploratory analysis, we did not adjust p values in our analysis.

Ethical considerations

Our study was approved by an ethics committee of a national university in Japan. Furthermore, all procedures were conducted in accordance with guidelines for studies involving human participants, the ethical standards of the institutional research

1
2
3 385 committee, and the revised 1964 Helsinki declaration and its later amendments or
4
5
6 386 comparable ethical standards.
7

8 9 387 **Results**

10 11 388 **Comparison of genuine synchrony and pseudo synchrony (Hypothesis 0)**

12
13
14 389 We compared symmetrical, complementary, and absolute synchrony of facial
15
16
17 390 movements between real (genuine) and random (pseudo) pairs. Synchronies of facial
18
19
20 391 movements for the genuine pair were mostly lower than for the pseudo pair (Table 1).
21
22
23 392 Compared to complementary synchronies (4/10), symmetrical and absolute synchronies
24
25
26 393 showed high rates of significant differences (9/10, 8/10, respectively). These findings
27
28
29 394 indicate that symmetrical and absolute synchronies were more robust for facial
30
31
32 395 movements than the complementary synchronies.
33
34

35 396 Similarly, we compared symmetrical, complementary, and absolute synchrony
36
37
38 397 of facial expressions between real (genuine) and random (pseudo) pairs. The synchrony
39
40
41 398 of facial expressions for the genuine pair was also mostly lower than for the pseudo pair
42
43
44 399 (Table 2). Except for the complementary synchrony of disgust, the other synchronies
45
46
47 400 show that the synchrony of facial expressions for the genuine pair was significantly
48
49
50 401 lower than for the pseudo pair. These findings indicate that the synchrony of facial
51
52
53 402 expressions was robust regardless of the direction of synchrony.
54

55 403 **Relevance between facial expressions and movements (Hypothesis 2)**

56
57
58 404 Before we check correlations between facial movements and expressions, we
59
60
61
62
63
64
65

1
2
3 405 compared these movements and expressions between the participants and their therapist.
4
5
6 406 Tables 3 and 4 show the average of the participants' and the therapist's facial
7
8
9 407 movements. The therapist showed significantly higher facial movements than the
10
11
12 408 participants in all facial areas, including the jaw (*paired t* = -15.080, *p* < .001), right
13
14 409 eyebrow (*paired t* = -9.119, *p* < .001), left eyebrow (*paired t* = -8.578, *p* < .001), nasal
15
16
17 410 cavity (*paired t* = -23.715, *p* < .001), ridge of nose (*paired t* = -22.981, *p* < .001), right
18
19
20 411 eye (*paired t* = -13.042, *p* < .001), left eye (*paired t* = -18.668, *p* < .001), outer lip
21
22
23 412 (*paired t* = -20.210, *p* < .001), inner lip (*paired t* = -18.489, *p* < .001), and face (*paired t*
24
25
26 413 = -18.417, *p* < .001). These findings indicated that the therapist's face moved more
27
28
29 414 frequently and widely than the participants' during the interviews.
30
31

32 415 Similarly, we compared the facial expressions of the participants and the
33
34
35 416 therapist (Tables 3 and 4). Participants showed stronger disgust (*paired t* = 5.104, *p*
36
37
38 417 < .001), happy (*paired t* = 4.188, *p* < .001), surprise (*paired t* = 4.657, *p* < .001), and
39
40
41 418 neutral expressions (*paired t* = 7.590, *p* < .001) than their therapist. On the other hand,
42
43
44 419 the therapist showed stronger angry (*paired t* = -7.607, *p* < .001), scared (*paired t* =
45
46
47 420 -7.427, *p* < .001), and sad expressions (*paired t* = -14.479, *p* < .001) than his
48
49
50 421 participants. These findings indicated that distributions of facial expressions are
51
52
53 422 different between participants and their therapist.
54

55 423 Table 3 shows correlations between participants' facial expressions and their
56
57
58 424 facial movements. Their angry expressions were positively correlated with their jaw,
59
60
61
62
63
64
65

1
2
3 425 right eyebrow, left eyebrow, nasal cavity, ridge of nose, right eye, left eye, and total face
4
5
6 426 movements (Table 3). Furthermore, their sad expressions were positively correlated
7
8
9 427 with their jaw, left eyebrow, nasal cavity, ridge of nose, right eye, left eye, outer lips,
10
11
12 428 inner lips, and total face movements (Table 3). Moreover, their neutral facial
13
14
15 429 expressions were negatively correlated with all of their facial movements (Table 3).
16
17
18 430 These findings indicate that participants' facial movements were related to their
19
20
21 431 negative emotional expressions.

22
23 432 Table 4 shows correlations between the therapist's facial expressions and his
24
25
26 433 facial movements. In contrast to the participants' findings, the therapist's scared
27
28
29 434 expressions were negatively correlated with his jaw, left eyebrow, right eye, left eye,
30
31
32 435 and face movements. Furthermore, the therapist's happy expressions were positively
33
34
35 436 correlated with his nasal cavity, ridge of nose, outer lips, and inner lips movements.
36
37
38 437 These findings indicated that the therapist's facial movements were related to their
39
40
41 438 increased positive emotions and decreased negative emotions.

42
43
44 439 **Relevance between Therapeutic Alliance and NVS of Facial Movements**
45
46 440 **(Hypothesis 1 and 3A)**

47
48
49 441 Fig. 4A shows examples of symmetrical synchrony of left eye movements during a
50
51
52 442 structured psychotherapeutic interview for the high therapeutic alliance and low
53
54
55 443 therapeutic alliance scorers. The strong red area indicates strong symmetrical
56
57
58 444 synchronies. The examples imply that the high therapeutic alliance scorer's symmetrical
59
60
61
62
63
64
65

1
2
3 445 synchronies were weaker than those of the low therapeutic alliance scorer. Fig. 4B
4
5
6 446 shows examples of complementary synchrony of left eye movements during an
7
8
9 447 interview. The strong blue area indicates strong complementary synchronies. In contrast
10
11
12 448 to symmetrical synchrony, the examples imply that the high therapeutic alliance scorer's
13
14
15 449 complementary synchronies were stronger than those of the low therapeutic alliance
16
17
18 450 scorer. Table 5 also confirmed this tendency. The symmetrical synchronies of facial
19
20
21 451 movements, including eye and mouth movements, were negatively correlated with
22
23
24 452 therapeutic alliance, whereas the complementary synchronies of a facial movement,
25
26
27 453 including left eyebrow movements, were positively correlated with therapeutic alliance,
28
29
30 454 although several correlations did not reach significant levels. These findings indicated
31
32
33 455 that the symmetrical synchrony of facial movements was negatively correlated with
34
35
36 456 therapeutic alliance. Table 6 shows the correlations between therapeutic alliance and
37
38
39 457 absolute synchrony of facial movements. Unlike Table 5, Table 6 did not show any
40
41
42 458 significant relations between therapeutic alliance and absolute synchrony of facial
43
44
45 459 movements.

46
47 460 **Relevance between Therapeutic Alliance and NVS of Facial Expressions**
48
49 461 **(Hypothesis 3B)**
50

51
52 462 Table 7 shows the correlations between therapeutic alliance and synchrony of facial
53
54
55 463 expressions. The symmetrical synchronies of facial expressions, including angry, happy,
56
57
58 464 and neutral, were positively correlated with therapeutic alliance. Furthermore, the
59
60
61
62
63
64
65

1
2
3 465 complementary synchronies of facial expressions, including scared, happy, and sad,
4
5
6 466 were also positively correlated with therapeutic alliance. The correlations between
7
8
9 467 symmetrical synchrony and complementary synchrony were also positive regarding
10
11
12 468 angry, scared, sad, surprise, and neutral expressions (Table 7). These findings indicated
13
14
15 469 that both complementary and symmetrical synchronies of facial expressions were
16
17
18 470 positively correlated with therapeutic alliance.

19
20 471 **Prediction of Therapeutic alliance from NVS of Facial Movements and Facial**
21
22
23 472 **Expressions (Hypothesis 4)**

24
25
26 473 Before we test the hierarchical regression analysis on therapeutic alliance from the
27
28
29 474 synchrony of facial movements and expressions, we indicated the correlations among
30
31
32 475 them (Table 8). Table 8 shows that therapeutic alliance was positively correlated with
33
34
35 476 symmetrical synchrony of scared expressions, complementary synchrony of happy
36
37
38 477 expressions, and complementary synchrony of scared expressions. On the other hand,
39
40
41 478 therapeutic alliance was negatively correlated with the symmetrical synchrony of right
42
43
44 479 eye and left eye movements. Further, symmetrical synchrony of left eye movements was
45
46
47 480 negatively correlated with complementary synchrony of scared expressions,
48
49
50 481 symmetrical synchrony of happy expressions, and symmetrical synchrony of scared
51
52
53 482 expressions. These findings suggested that both symmetrical and complementary
54
55
56 483 synchronies of facial expressions were positively related to therapeutic alliance;
57
58
59 484 however, the symmetrical synchrony of right and left eye movements was negatively
60
61
62
63
64
65

1
2
3 485 related to therapeutic alliance.
4
5

6 486 Table 9 shows the hierarchical regression analysis on therapeutic alliance from
7
8
9 487 symmetrical and complementary synchronies. Model 1 predicted therapeutic alliance
10
11
12 488 from participants' age and sex only. Model 2 included both the participants' and the
13
14
15 489 therapist's facial movements and expressions as independent variables. Model 3
16
17
18 490 included complementary and symmetrical synchronies of happy and scared emotions as
19
20
21 491 independent variables. Model 3 also included complementary and symmetrical
22
23
24 492 synchronies of right and left eye movements as independent variables. Model 2
25
26
27 493 indicated that participants' happy expressions during the interviews predicted a positive
28
29
30 494 therapeutic alliance, whereas the therapist's scared expression during the interviews
31
32
33 495 predicted a negative therapeutic alliance. Further, model 3 also indicated that inclusion
34
35
36 496 of complementary and symmetrical synchronies increased the contribution rate
37
38
39 497 significantly (Table 9). Further, symmetrical synchrony of left eye movements predicted
40
41
42 498 a negative therapeutic alliance; however, complementary synchrony of left eye
43
44
45 499 movements predicted a positive therapeutic alliance. Table 10 used absolute synchronies
46
47
48 500 of facial expressions and movements, and predicted therapeutic alliance similar to Table
49
50
51 501 9. Unlike Table 9, model 3 did not increase the contribution rate.

52 502 **Discussion**

53
54
55 503 The current study used video imaging methods and quantified facial movements and
56
57
58 504 facial expressions for every 100 milliseconds. Our machine-based method measured
59
60
61
62
63
64
65

1
2
3 505 facial movements and expressions precisely within a short time and without a human
4
5
6 506 rater's bias (Bernieri et al., 1994), similar to previous studies (Arriaga et al., 2017; Levi
7
8
9 507 & Hassner, 2015; Matsugu et al., 2003; Ramseyer & Tschacher, 2011; Schmidt et al.,
10
11
12 508 2012). Our extension of participants into the Asian population is also important for
13
14
15 509 generalizing the findings of NVS (Bernieri, 1988; Condon & Ogston, 1966; Gatewood
16
17
18 510 & Rosenwein, 1981; Lakin & Chartrand, 2003), similar to a previous study (Kimura &
19
20
21 511 Daibo, 2006). Our findings can summarize the genuine synchrony, speaker role,
22
23
24 512 symmetry/complementary synchrony, and the meaning of NVS with regards to facial
25
26
27 513 parts.

28
29 514 **Lower Scores of Synchrony for Genuine Pairs than for Pseudo Pairs (Hypothesis**
30
31
32 515 **0)**

33
34
35 516 Our study confirmed that the synchrony of facial movements for the genuine pair was
36
37
38 517 significantly different from the synchrony of the pseudo pair. Yet, our study found that
39
40
41 518 the synchrony of facial movements was lower for genuine pairs than for pseudo pairs,
42
43
44 519 although previous studies of body movements supported that the synchrony of
45
46
47 520 movements was higher for genuine pairs than for the pseudo pairs (Kupper et al., 2015;
48
49
50 521 Lavelle et al., 2013; Paulick et al., 2018; Tschacher & Pfammatter, 2016). The
51
52
53 522 inconsistency of the findings between current and previous studies comes from the
54
55
56 523 differences of active frames between these movements. The body movements were
57
58
59 524 mostly inactive for most frames (a frame is 100 milliseconds) and became rapidly active
60
61
62
63
64
65

1
2
3 525 for specific frames (Tschacher et al., 2014). The random pairs of body movements
4
5
6 526 missed these specific active frames, so the synchrony of pseudo pairs was lowered. On
7
8
9 527 the other hand, facial movements were mostly active during most frames; these frames
10
11
12 528 were regarded as active frames (Fig.1 D, Table 3, and Table 4). Consequently, the
13
14
15 529 random pairs of facial movements did not miss the active frames. Furthermore, the
16
17
18 530 pseudo pairs involved so many individuals that individual differences of pseudo pairs
19
20
21 531 could increase the deviation from the average, which directly increases the size of
22
23
24 532 synchrony among the pseudo pairs. As a result, the synchrony of pseudo pairs in facial
25
26
27 533 movements could be increased. The same discussion can be applicable in
28
29
30 534 electromyography-based emotion encoding (Riehle et al., 2017) and machine-based
31
32
33 535 emotion encoding. The former's active frames were rare because of a high threshold of
34
35
36 536 activation (Riehle & Lincoln, 2018), whereas the latter's active frames were frequent
37
38
39 537 because it had no threshold of activation.

40
41 538 **Speaker role moderates the relevance between facial movements and facial**
42
43
44 539 **expressions (Hypothesis 2)**

45
46
47 540 Our study also confirmed the links between eye movements and negative emotions
48
49
50 541 among participants. Like previous studies (Baron-Cohen et al., 2001; D'Mello et al.,
51
52
53 542 2007; Lee et al., 2014), participants' eye movements were linked with angry and sad
54
55
56 543 expressions. Diagnostic interviews by a clinical psychologist are considered to be
57
58
59 544 stressful for the participants. Hence, it is natural that their facial movements were linked
60
61
62
63
64
65

1
2
3 545 with these negative facial expressions. On the other hand, our study did not confirm the
4
5
6 546 links of eye movements with regards to the clinical psychologist. Actually, his eye
7
8
9 547 movements were negatively linked with his scared expression (Table 4). Further, his
10
11
12 548 outer and inner lip movements were positively linked with his happy expression, which
13
14
15 549 did not appear in these participants (Table 3, 4). The inconsistency of facial expressions
16
17
18 550 between the participants and therapist might come from role differences. During the
19
20
21 551 diagnostic interview, the psychologist has to build therapeutic alliance with his
22
23
24 552 participants, so he intentionally interacts with the participants (Elvins & Green, 2008;
25
26
27 553 Martin et al., 2000). Actually, the volume of his facial movement was higher than the
28
29
30 554 volume of the facial movement by the participants (Table 3, 4). Further, his eye
31
32
33 555 movements were also more rapid than the participants' eye movements (Fig1.D). These
34
35
36 556 data indicated that a diagnostic interview motivated him to build a therapeutic alliance;
37
38
39 557 consequently, his movements might be linked with prosocial emotional expressions
40
41
42 558 rather than negative emotional expressions. Still, our therapist's data was only from a
43
44
45 559 male therapist so these findings might be originated from a peculiarity of him. Hence,
46
47
48 560 generalization of current relevance between therapist's facial movements and facial
49
50
51 561 expressions (Table 4) needs caution.

52 **Complementary and Symmetrical Synchronies of Facial Movements and Facial**
53
54
55 563 **Expressions (Hypothesis 1, 3A, 3B)**
56

57
58 564 Unlike NVS of many movements (Bernieri, 1988; McFarland, 2001; Miles et al., 2011;
59
60
61
62
63
64
65

1
2
3 565 Repp & Su, 2013; Semin & Cacioppo, 2008; Vacharkulksemsuk & Fredrickson, 2012;
4
5
6 566 Vicaria & Dickens, 2016; Won et al., 2014), we did not find any link between absolute
7
8
9 567 synchrony of facial movements and therapeutic alliance (Table 6). Detailed analysis also
10
11
12 568 found that complementary synchrony of facial movements was positively linked with
13
14
15 569 therapeutic alliance, whereas symmetrical synchrony was negatively linked with
16
17
18 570 therapeutic alliance (Table 5). These findings indicated that absolute synchrony of facial
19
20
21 571 movements cancelled the positive effects of complementary synchrony and the negative
22
23
24 572 effects of symmetrical synchrony on therapeutic alliance, so that no significant link was
25
26
27 573 found between the absolute synchrony of facial movements and therapeutic alliance.
28
29
30 574 Still, it is unclear why symmetrical and complementary synchrony of facial expressions
31
32
33 575 indicated correlations with therapeutic alliance in the same direction (Table 7), while the
34
35
36 576 synchrony of facial movements did not (Table 5).

37
38 577 This inconsistency can be explained by the stability of facial expressions and
39
40
41 578 volatility of facial movements. For encoding of facial expressions, emotion-relevant
42
43
44 579 facial movements were selected and emotion-irrelevant facial movements were
45
46
47 580 discarded. Meanwhile, for encoding of facial movements, all facial movements were
48
49
50 581 encoded. This indicates that all one's facial movements affected all the other's facial
51
52
53 582 movements; that is, NVS of facial movements is volatile. The volatility of NVS of facial
54
55
56 583 movements might require a sensitive index, such as complementary and symmetrical
57
58
59 584 synchronies, to capture these NVSs. In contrast, one's emotional-irrelevant facial
60
61
62
63
64
65

1
2
3 585 movements did not affect the other's facial expressions; that is, NVS of facial
4
5
6 586 expressions is stable regarding emotional-irrelevant facial movements. The stability of
7
8
9 587 the NVS of facial expressions might require total volume, such as the absolute values of
10
11
12 588 synchronies, to capture these NVSs. Hence, absolute values of synchronies fit well with
13
14
15 589 the NVS of facial expressions, but not with the NVS of facial movements (Table 8).
16
17
18 590 Although complementary and symmetrical synchronies might be necessary for
19
20
21 591 assessing the NVS of facial movements, they could also be useful for assessing the NVS
22
23
24 592 of body movements. If complementary and symmetrical communication synchronies
25
26
27 593 exist in NVS of body movements, symmetrical synchronies might be prevalent in
28
29
30 594 competitive settings (Lozza et al., 2018; Tschacher et al., 2014), whereas
31
32
33 595 complementary synchronies might be prevalent in collaborative settings (Bernieri,
34
35
36 596 1988; Ramseyer & Tschacher, 2011; Shockley et al., 2003). Further, reanalysis of head
37
38
39 597 movements from the perspective of symmetrical and complementary synchronies is also
40
41
42 598 interesting (Ramseyer & Tschacher, 2014). Testing these hypotheses is important to
43
44
45 599 clarify the direction of synchrony associated with NVS.

46
47 600 **Meanings of NVS with regards to Facial Movements and Expressions (Hypothesis**

48
49 601 **4)**

50
51
52 602 Complementary and symmetrical synchronies of scared expressions were positively
53
54
55 603 linked with therapeutic alliance. Furthermore, symmetrical synchrony of happy
56
57
58 604 expressions was positively linked with therapeutic alliance, same as symmetrical
59
60
61
62
63
64
65

1
2
3 605 synchrony of scared expressions. Absolute synchronies of happy and scared expressions
4
5
6 606 were also positively correlated with therapeutic alliance. These findings indicated that
7
8
9 607 the total synchrony of facial expressions is linked with therapeutic alliance, regardless
10
11
12 608 of synchrony directions (symmetrical or complementary) and emotional values (positive
13
14
15 609 or negative emotions). The synchrony of facial expressions might be regarded as an
16
17
18 610 emotional interaction between participants and the therapist, which positively affect
19
20
21 611 therapeutic alliance (Elvins & Green, 2008; Martin et al., 2000). Many studies have
22
23
24 612 found that one's mimicking of another's facial expressions affect one's emotional
25
26
27 613 experience and the collaborative relationship between them (Chartrand & Bargh, 1999;
28
29
30 614 Chartrand & Lakin, 2013; Shockley et al., 2003). Symmetrical synchrony of facial
31
32
33 615 expressions during an interview can be regarded as mimicry of facial expressions
34
35
36 616 between the participants and the therapist within a 2 second delay, similar to previous
37
38
39 617 studies (Riehle et al., 2017; Riehle & Lincoln, 2018). Our study measured the
40
41
42 618 synchrony at 100 milliseconds; consequently, most synchronies could be regarded as at
43
44
45 619 unconscious level (Lakin & Chartrand, 2003). Complementary synchrony of facial
46
47
48 620 expressions was positively related to symmetrical synchrony of facial expressions
49
50
51 621 (Table 7); consequently, the complementary synchrony of facial expressions could be
52
53
54 622 regarded as a by-product of mimicry of facial expressions.

55 623 Contrary to NVS of facial expressions, symmetrical synchrony of left eye
56
57
58 624 movements was negatively correlated with therapeutic alliance. Hierarchical regression
59
60
61
62
63
64
65

1
2
3 625 models also confirmed that symmetrical synchrony of left eye movements predicted a
4
5
6 626 negative therapeutic alliance. Further, symmetrical synchrony of left eye movements
7
8
9 627 was negatively related to complementary synchrony of scared expressions, symmetrical
10
11
12 628 synchrony of happy expressions, and symmetrical synchrony of scared expressions.
13
14 629 When we regard the synchrony of facial expressions as an emotional interaction
15
16
17 630 between the participants and the therapist (Chartrand & Bargh, 1999; Chartrand &
18
19
20 631 Lakin, 2013; Shockley et al., 2003), symmetrical synchrony of left eye movements can
21
22
23 632 be regarded as a blocker of emotional interaction between them. Our model also found
24
25
26 633 that the complementary synchrony of left eye movements positively predicted
27
28
29 634 therapeutic alliance. These findings indicate that complementary synchrony of left eye
30
31
32 635 movements could be smooth emotional turn taking, whereas the symmetrical synchrony
33
34
35 636 of left eye movements was conflict of emotional turn taking. NVS of left eye
36
37
38 637 movements can be an index of emotional turn taking at a micro visual level.
39
40
41 638 Interestingly, symmetrical synchrony of inner and outer lips was also negatively
42
43
44 639 correlated with therapeutic alliance. The symmetrical synchrony of mouth movements
45
46
47 640 might imply an error of turn taking and an increased number of cross-talk. These
48
49
50 641 findings also indicated that symmetrical synchrony of eye and mouth movements might
51
52
53 642 be a blocker index of emotional turn taking. The current findings extended the index of
54
55
56 643 emotional turn taking from the prosody level (Acosta & Ward, 2011) to the micro visual
57
58
59 644 level. Still, coefficients of therapist's left eye movement were deviant from those in his
60
61
62
63
64
65

1
2
3 645 other movements and participants' movements (Table 3 and 4), the current findings
4
5
6 646 might be originated from a peculiarity of the interviewer. Hence, generalization of
7
8
9 647 synchrony of left eye movements during therapy (Table 8, 9 and 10) needs caution.

10
11 648 **Limitations**

12
13
14 649 Despite these positive findings and implications, our study had four limitations. First,
15
16
17 650 our therapist was unaware of the current hypothesis because he had another hypothesis
18
19
20 651 during the experiment (Yokotani et al., 2018); however, he was not naive to the current
21
22
23 652 research question because he was a main analyzer and main writer of our paper. Hence,
24
25
26 653 the therapist might have been biased as an experimenter, even though the control of eye
27
28
29 654 movements every 100 milliseconds during the interview might have been impossible.
30
31
32 655 Second, encoding of facial expressions was still under development. Especially,
33
34
35 656 differentiation between negative emotions was still difficult for machines because
36
37
38 657 several areas, such as a frown, were quite similar to angry and disgust expressions
39
40
41 658 (Arriaga et al., 2017). Further, machine learning from a Western face database might not
42
43
44 659 fit well with an emotion recognition of Asian faces (Carrier et al., 2013). Addition of
45
46
47 660 Asian faces to the database is required for further study. Third, our setting had only one
48
49
50 661 male therapist with glasses; thus, we could not clarify the gender effect, especially
51
52
53 662 among female participant-female therapist pairs. Gender differences might affect NVS
54
55
56 663 of facial movements (Stratou, Hoegen, Lucas, & Gratch, 2017). The gender effects need
57
58
59 664 to be controlled. Further, our emotion recognition model frequently confused the
60
61
62
63
64
65

1
2
3 665 therapist's dark glass frames with his frowning (Arriaga et al., 2017), so the model
4
5
6 666 wrongly believes that he is frowning and mistakenly overestimate the probability of his
7
8
9 667 angry expression; the effects of glasses also need to be controlled. Therefore, future
10
11
12 668 studies should include female therapists and therapists without glasses. Fourth, we did
13
14
15 669 not include verbal data; therefore, we cannot adjust the verbal effect, such as cross-talk,
16
17
18 670 on symmetrical synchrony of facial movements and therapeutic alliance. Addition of
19
20
21 671 verbal data analysis could purify the nonverbal effects of synchrony regarding facial
22
23
24 672 movements and expressions on therapeutic alliance.

673 **Conclusion**

25
26
27
28
29 674 Our study analyzed NVS of both facial expressions and facial movements using video
30
31
32 675 imaging techniques (Bradski & Kaehler, 2000; King, 2009; Yokotani et al., 2018),
33
34
35 676 standardized face (Langlois & Roggman, 1990), and normalized cross-correlations (Yoo
36
37
38 677 & Han, 2009). We established two points. First, NVS of facial expressions during the
39
40
41 678 interviews indicated an emotional interaction between the participants and the therapist.
42
43
44 679 Taking into account that a frame is 100 milliseconds, the emotional interaction can be at
45
46
47 680 an unconscious level. Hence, NVS of facial expressions can be regarded as an index of
48
49
50 681 emotional interaction at an unconscious level (Lakin & Chartrand, 2003). Second,
51
52
53 682 symmetrical synchrony of left eye movements predicted a negative therapeutic alliance.
54
55
56 683 Further, the symmetrical synchrony of left eye movements was also negatively related
57
58
59 684 to the synchrony of facial expressions. These findings indicated that the symmetrical
60
61
62
63
64
65

1
2
3 685 synchrony of left eye movements can be a blocker of emotional interaction. In other
4
5
6 686 words, symmetrical synchrony of left eye movements might be a negative predictor of
7
8
9 687 therapeutic alliance, similar to previous studies (de la Peña, Friedlander, Escudero, &
10
11
12 688 Heatherington, 2012; Escudero et al., 1997; Heatherington & Friedlander, 1990;
13
14 689 Watzlawick et al., 2011), although the synchrony of most parts was a positive predictor
15
16
17 690 of therapeutic alliance (Paladino et al., 2010; Repp & Su, 2013; Semin & Cacioppo,
18
19
20 691 2008; Vicaria & Dickens, 2016). These findings need to be replicated in a future study
21
22
23 692 with a new dataset.

24
25
26 693 The video imaging technique that we used (Ramseyer & Tschacher, 2011;
27
28
29 694 Yokotani et al., 2018) could reduce the cost and time for evaluation of NVS and provide
30
31
32 695 detailed analysis of NVS (Bernieri, 1988; Condon & Ogston, 1966; Gatewood &
33
34
35 696 Rosenwein, 1981; Lakin & Chartrand, 2003). Addition of facial movements and
36
37
38 697 expression to the NVS studies could extend previous findings of NVS of body/head
39
40
41 698 movements (Kupper et al., 2015; Paulick et al., 2017, 2018; Ramseyer & Tschacher,
42
43
44 699 2014) to NVS of facial movements (Hughes & Aung, 2018; Künecke, Wilhelm, &
45
46
47 700 Sommer, 2017; Riehle et al., 2017) and contribute to the understanding of nonverbal
48
49
50 701 behavior in dyadic relationships (Schmidt et al., 2012; Won et al., 2014).

51

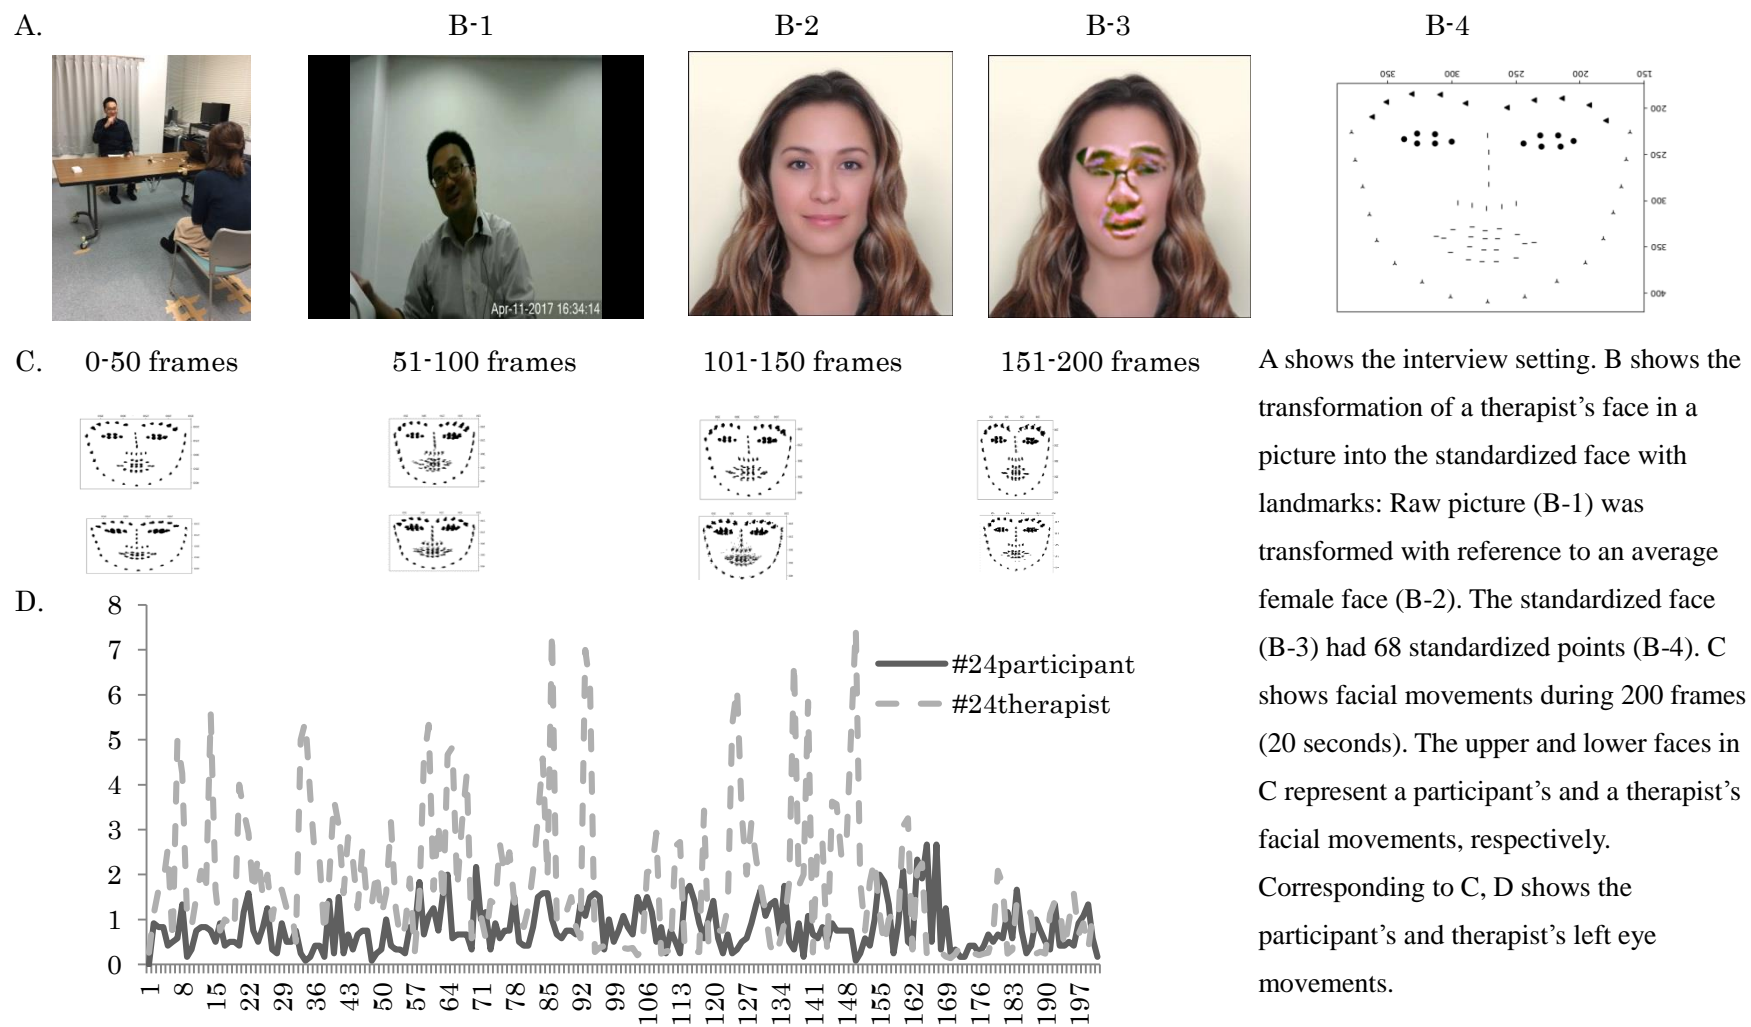

Fig. 1. Experimental setting and an example analysis of facial movements

Shaking Head

Nodding

Approach (or, avoidance)

When a participant shakes his or her head, the head will be rotated (θ). When the participant nods, the head will be moved (t_x, t_y). Further, when the participant approaches the camera, his or her facial size will be expanded (d_x, d_y). These head movements change the positions of facial landmarks, regardless of actual facial movements. To minimize the effects of these head movements on facial movements, we performed a coordinate transformation from captured positions of facial landmarks (x, y) to the transferred facial landmarks (x', y') through an affine formula:

$$[x', y', 1] = [x, y, 1] \begin{bmatrix} dx \cos \theta & \sin \theta & 0 \\ -\sin \theta & dy \cos \theta & 0 \\ tx & ty & 1 \end{bmatrix}$$

Note: The $\theta, d_x, d_y, t_x,$ and t_y were estimated through averaged female face and ordinary procrustes analysis.

Fig. 2. Affine formula was used to prevent the effects of head movements on facial movements

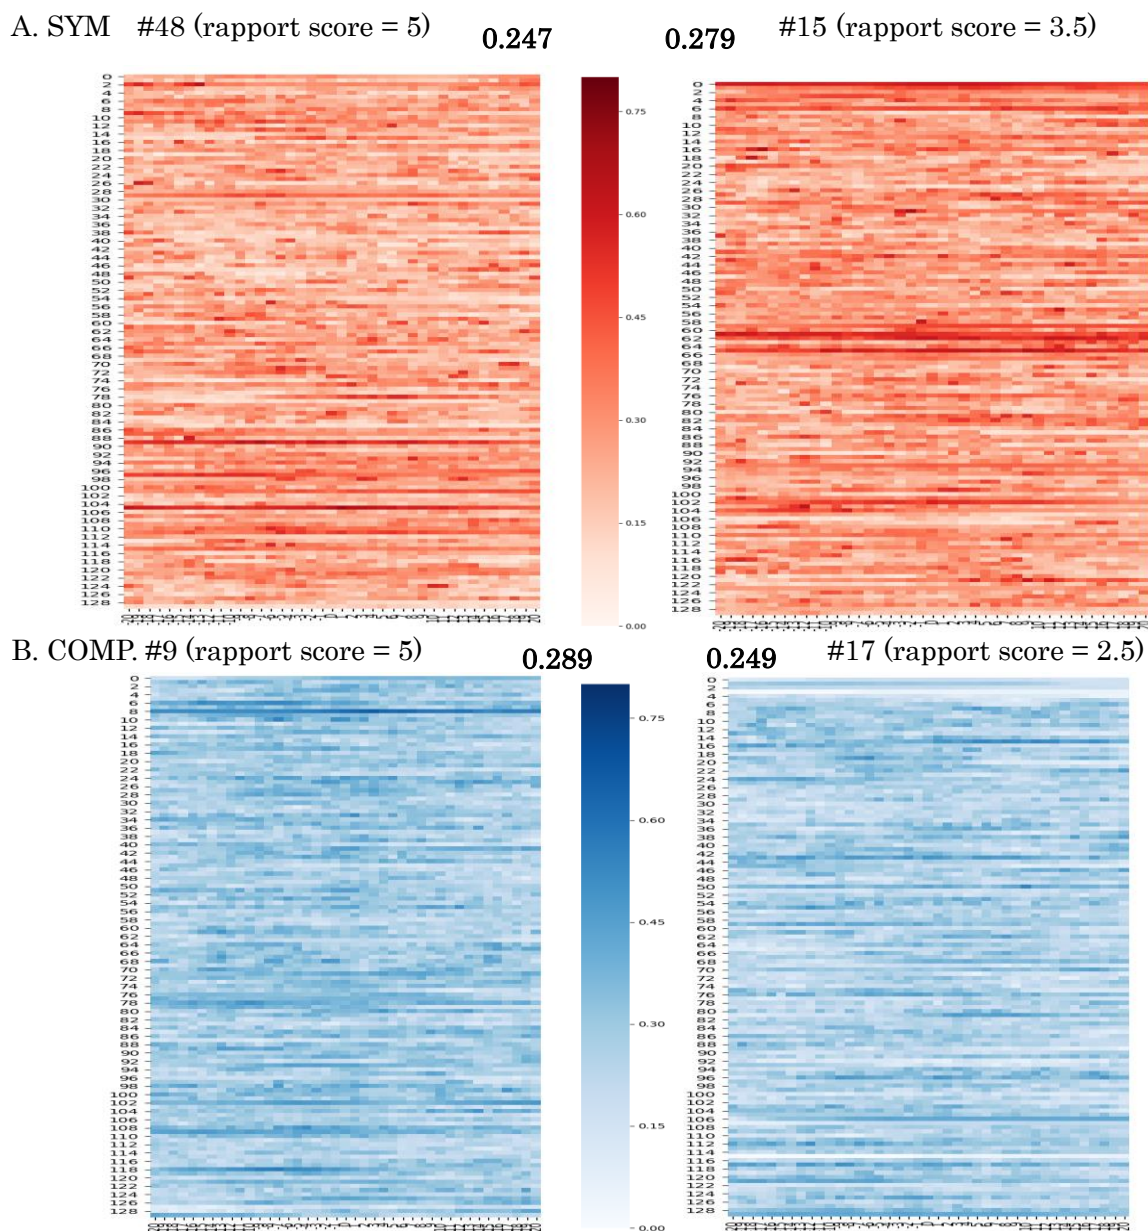

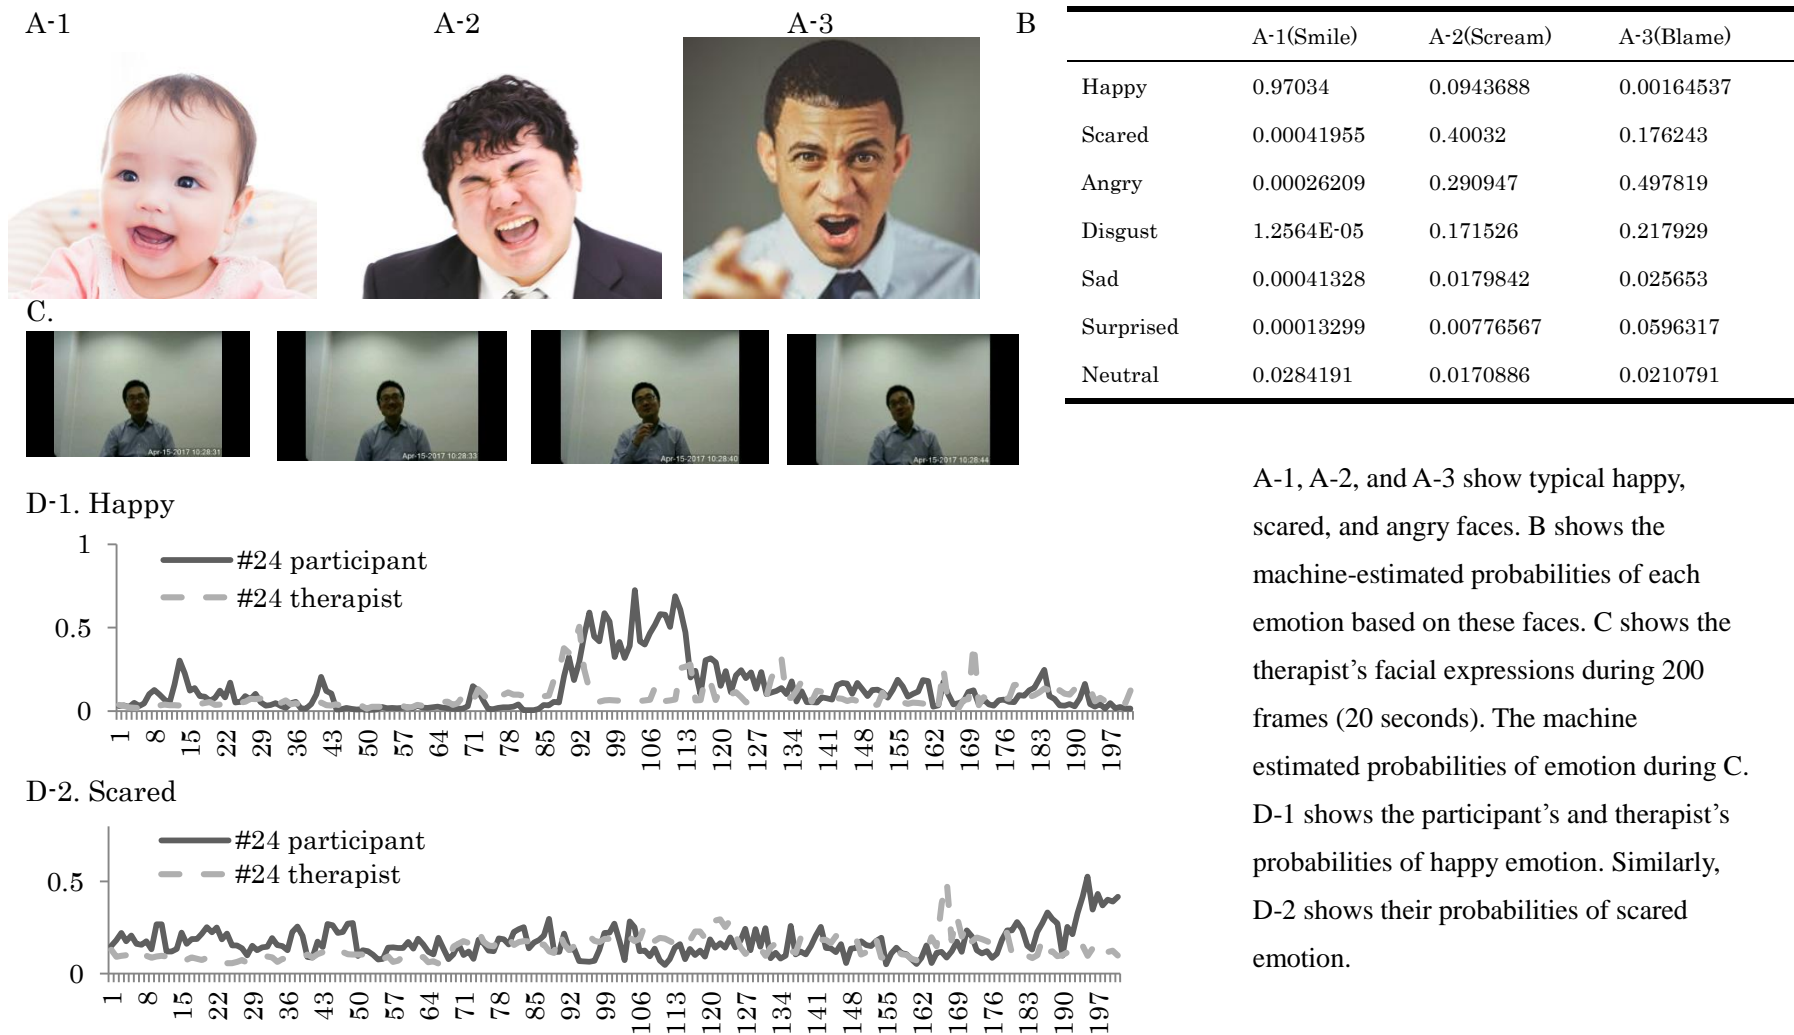

Fig.3. Sixty eight landmarks on a face

Notes: These landmarks indicate the jaw (marks 1–17), eyebrows (right eyebrow: marks 18–22; left eyebrow: marks 23–27), nose (nasal cavity: marks 28–31; ridge of nose: marks 32–36), eyes (right eye: marks 37–42; left eye: marks 43–48), mouth (outer lip: marks 49–60; inner lip: marks 61–68), and face (marks:1-68).

A shows symmetrical synchrony of left eye movements between clients (#48 with a high rapport score, #15 with a low rapport score) and a therapist. The strong red color indicates strong symmetrical synchrony. The y-axis indicates the duration of each session (1 unit includes 70 frames [7 seconds]). The x-axis indicates the synchrony time lag between the therapist and client: -20 indicates that the therapist's movement was delayed for 20 frames (2 seconds) compared to the client's movement, whereas 20 indicates therapist's movement was ahead by 20 frames. The bold scores indicate the total average of symmetrical synchrony during the session. Similarly, B shows complementary synchrony of left eye movements between clients and a therapist. The strong blue color indicates strong complementary synchrony. SYM: Symmetrical synchrony, COMP: Complementary Synchrony

Fig. 4. Synchrony of left eye movements during an interview

A-1, A-2, and A-3 show typical happy, scared, and angry faces. B shows the machine-estimated probabilities of each emotion based on these faces. C shows the therapist's facial expressions during 200 frames (20 seconds). The machine estimated probabilities of emotion during C. D-1 shows the participant's and therapist's probabilities of happy emotion. Similarly, D-2 shows their probabilities of scared emotion.

Fig. 5. Encoding of facial expression and an example analysis of facial expressions

ΔR^2	.089	+	.260	*	.227	*

Notes ^a: *df* = 2, 52; ^b: *df* = 10, 44, ^c: *df* = 18, 36. ^d: Volume of right eyes (Th.) had high variance inflation factors (Model2 = 8.460, Model3 = 14.120), so coefficients of volume of right eyes (Th.) were high but did not reach significant levels. Par.: Participant, Th.: Therapist, SYM.: Symmetrical synchrony, COMP.: Complementary synchrony, **: *p* < .01, *: *p* < .05, +: *p* < .10

Table 10. Hierarchical Regression Analysis on Therapeutic Alliance from Absolute Synchrony

	model1		model2		model3	
Age	-0.176		-0.087		-0.018	
Sex	-0.242	+	-0.035		-0.015	
Happy(Par.)			.369	*	.302	+
Happy(Th.)			.060		.229	
Scared(Par.)			.167		.102	
Scared(Th.)			-0.466	*	-0.458	*
V. right eye(Par.)			-0.094		-0.131	
V. left eye (Par.)			.004		.083	
V. right eye(Th.) ^d			-0.526		-0.476	
V. left eye (Th.)			.158		.157	
ABS. Happy					-0.149	
ABS. Scared					.384	
ABS. Right eye					-0.138	
ABS. Left eye					.059	
<i>F</i>	2.526 ^a	+	2.358 ^b	*	2.014 ^c	*
<i>adjusted R</i> ²	.053		.201		.208	
<i>R</i> ²	.089		.349		.413	
ΔR^2	.089	+	.260	*	.065	

Notes ^a: *df* = 2, 52; ^b: *df* = 10, 44, ^c: *df* = 18, 36, ^d: Volume of right eyes (Th.) had high VIF (Model2 = 8.460, Model3 = 10.673); consequently, coefficients of volume of right eyes (Th.) were high but did not reach significant levels. Par.: Participant, Th.: Therapist, ABS.: Absolute Synchrony, **: *p* < .01, *: *p* < .05, +: *p* < .10
